The manipulation of two 2nd-order quantum pathways has been successfully demonstrated experimentally in atomic Rubidium. This work would explore the coherent control of pathways in the quantum system with N intermediate states connecting the initial and target states. A $4N$-block scheme is proposed to control the N 2nd-order pathways which are driven by a weak broadband pulse. The model with $N=3$ is given as an example to demonstrate our strategy. In this scheme, boundaries of the spectral blocks are functions of the resonant frequencies, and the resonant and non-resonant contributions interfere mutually to achieve the quantum pathway control effectively. The simple strategy may provide a practical choice for pathway manipulation experiments since there are only $2N$ phase variables to adjust.

Key words: Coherent control, Multiple 2nd-order, Quantum pathway

I. INTRODUCTION

Due to its scientific importance and potential applications, quantum dynamics control has been an attractive field [1–5]. In many laser experiments, coherent control of an observable is often achieved by adjusting the interference among different quantum pathways [6, 7]. Thus, it is important to investigate pathway manipulation in quantum systems. Recently, Rey-de-Castro \textit{et al.} have successfully controlled the ratio of two 2nd-order quantum pathways in Rubidium [8]. Their experiments show the quantum pathway dynamics can be steered towards the desired direction by phase shaping of broadband femtosecond pulses. We have also investigated the cooperation and competition between pathways in the optimal control of Rubidium [9].

Silberberg \textit{et al.} have proposed that a resonant two-photon absorption (TPA) rate can be enhanced via constructive interference between resonant and non-resonant contributions [10]. In their work, a three-level ladder configuration is employed with only one 2nd-order pathway involved. Based on Silberberg’s work, Lee \textit{et al.} have proposed an eight-block scheme to maximize the fluorescence signal from the target state for a four-level diamond configuration system with two 2nd-order pathways involved [11].

In this work, we further study the manipulation of multiple 2nd-order pathways. Compared with the transform limited pulses (TLPs), the $4N$ block scheme with only $2N$ phase variables to adjust can achieve much better effects, as illustrated by an example with three intermediate states.

II. THEORETICAL MODEL

We consider a quantum system with \textit{N} intermediate states connecting the initial stand target states. The Hamiltonian is the form of $H=H_0-\mu E(t)$, where $H_0$ is the unperturbed Hamiltonian with eigenstates $|l_p\rangle$ ($p=0, 1, \ldots, \textit{N}, \textit{N}+1$), $\mu$ is the dipole moment operator, and $E(t)$ is the control field. In the basis $\{|l_p\rangle\}$, the matrices $H_0$ and $\mu$ are given by

$$H_0 = \begin{bmatrix} 0 & 0 & 0 & \cdots & 0 & 0 \\ 0 & \omega_1 & 0 & \cdots & 0 & 0 \\ 0 & 0 & \omega_2 & \cdots & 0 & 0 \\ \vdots & \vdots & \vdots & \ddots & \vdots & \vdots \\ 0 & 0 & 0 & \cdots & \omega_{N-1} & 0 \\ 0 & 0 & 0 & \cdots & 0 & \omega_{N+1} \end{bmatrix}$$ (1)

$$\mu = \begin{bmatrix} 0 & \mu_1 & \mu_2 & \cdots & \mu_N & 0 \\ \mu_1 & 0 & 0 & \cdots & 0 & \mu'_1 \\ \mu_2 & 0 & 0 & \cdots & 0 & \mu'_2 \\ \vdots & \vdots & \vdots & \ddots & \vdots & \vdots \\ \mu_N & 0 & 0 & \cdots & 0 & \mu'_N \\ 0 & \mu'_1 & \mu'_2 & \cdots & \mu'_N & 0 \end{bmatrix}$$ (2)

where atomic units are adopted with $\hbar=1$. The initial state is $|l_0\rangle$ with zero energy, and the target state is $|l_{N+1}\rangle$ with energy $\omega_{N+1}$. There are $N$ intermediate states $|l_p\rangle$ ($p=1, \ldots, N$). An example system with $N=3$ is shown in Fig.1(a).

The dynamics in the interaction representation are

FIG. 1 (a) Energy level structure of the example system. The three 2nd-order pathways are $|l_{0}\rangle \rightarrow |l_{1}\rangle \rightarrow |l_{4}\rangle$, $|l_{0}\rangle \rightarrow |l_{2}\rangle \rightarrow |l_{4}\rangle$, and $|l_{0}\rangle \rightarrow |l_{3}\rangle \rightarrow |l_{4}\rangle$. (b) Spectrum of the laser pulse ($E_{0}(\omega)$ in Eq.(8)) employed in our theoretical studies. The spectrum is divided into 12 blocks in our strategy, and the vertical lines indicate the spectral boundaries. Each block has a constant phase.

In the perturbation regime, $N$ 2nd-order pathways, $|l_{0}\rangle \rightarrow |l_{p}\rangle \rightarrow |l_{N+1}\rangle$ $(p=1, \cdots, N)$, dominate the excitation from the initial state $|l_{0}\rangle$ to the target state $|l_{N+1}\rangle$. The corresponding amplitudes are given by the following $N$ 2nd-order Dyson expansion terms of $U_{1}(t)$,

$$U_{p}(T) = - \mu_{p} \mu_{p}' \int_{-\infty}^{T} \exp[i(\omega_{N+1} - \omega_{p})t_{2}]E(t_{2}) \cdot$$

$$\int_{-\infty}^{t_{2}} \exp[i\omega_{p}t_{1}]E(t_{1})dt_{1}dt_{2},$$

$$p = 1, 2, \cdots, N \quad (5)$$

The final amplitude of each pathway after the pulse is over ($T \rightarrow \infty$) can be written in the frequency domain as combination of resonant part $U_{p}^{r}$ and non-resonant part $U_{p}^{nr}$ [10]

$$U_{p}(T \rightarrow \infty) = U_{p}^{r} + U_{p}^{nr} \quad (9)$$

$$= \mu_{p} \mu_{p}' \left[ - \pi E(\omega_{p})E(\omega_{N+1} - \omega_{p}) + i\varphi \int_{-\infty}^{\infty} \frac{E(\omega)E(\omega_{N+1} - \omega)}{\omega_{p} - \omega} d\omega \right] \quad (6)$$

here $\varphi$ is the principal value of Cauchy. Then the total transition probability from the initial state $|l_{0}\rangle$ to the target state $|l_{N+1}\rangle$ after the pulse being off is

$$P_{f} = |\langle l_{N+1} | U_{1}(T \rightarrow \infty, 0) | l_{0}\rangle |^{2} \quad (7)$$

III. PATHWAY MANIPULATION STRATEGY

To mimic the experimental conditions, a laser field with a Gaussian envelope is employed in our studies:

$$E(\omega) = E_{0}(\omega) \exp{i\varphi(\omega)} \quad (8)$$

$$E_{0}(\omega) = B \exp\left[\frac{-(\omega - \omega_{0})^{2}}{\Delta^{2}}\right] \exp[i\varphi(\omega)] \quad (9)$$

here the parameter $B$ is taken to be 0.0006 a.u., small enough to make sure that the light-atom interaction is perturbative. In our strategy, only the phase $\varphi(\omega)$ is adjusted to control the quantum pathways.

As shown in Eq.(6), each pathway amplitude can be divided into the resonant and non-resonant parts, and thus it can be modulated by changing the interference of these terms. Our pathway manipulation strategy is based on this idea, and one five-level quantum system will be used as an example in the following for demonstration.

The example system is shown in Fig.1(a) with the parameters in Eq.(1) and Eq.(2) being $\mu_{1}=0.95$, $\mu_{2}=1.01$, $\mu_{3}=1.1$, $\mu_{1}'=1.22$, $\mu_{2}'=1.15$, $\mu_{3}'=1.06$, $\omega_{1}=0.0573$ ($\sim 795$ nm), $\omega_{2}=0.0579$ ($\sim 787$ nm), $\omega_{3}=0.0585$ ($\sim 779$ nm), and $\omega_{4}=0.118$ ($\sim 386$ nm). The spectrum of the laser pulse employed in our studies is shown in Fig.1(b), with the central frequency $\omega_{0}$ and full width at half maximum (FWHM) of the pulse being 0.0583 ($\sim 782$ nm) and 0.00335 ($\sim 45$ nm), respectively.

Three 2nd-order pathways, namely $|l_{0}\rangle \rightarrow |l_{1}\rangle \rightarrow |l_{4}\rangle$, $|l_{0}\rangle \rightarrow |l_{2}\rangle \rightarrow |l_{4}\rangle$, and $|l_{0}\rangle \rightarrow |l_{3}\rangle \rightarrow |l_{4}\rangle$, dominate the population transfer from the initial state $|l_{0}\rangle$ to the target state $|l_{4}\rangle$. The non-resonant term of the $p$th ($p=1, 2, 3$) pathway is

$$U_{p}^{nr} = i\mu_{p} \mu_{p}' \varphi \int_{-\infty}^{\infty} \left\{ \frac{E_{0}(\omega)E_{0}(\omega_{4} - \omega)}{\omega_{p} - \omega} \right\} \exp[i\varphi(\omega)] d\omega \quad (10)$$

Then the total non-resonant contribution is
$$U^{nr} = i\phi \int_{-\infty}^{\infty} \{ f(\omega) E_0(\omega) E_0(\omega_4 - \omega) \exp[i\phi(\omega)] \} \exp[i\phi(\omega_4 - \omega)] d\omega$$ (11)

$$f(\omega) = \sum_{p=1}^{3} \frac{\mu_p \mu_p^*}{\omega_p - \omega} \omega - \omega_1) + \omega - \omega_2)$$

$$\omega_1 \text{ and } \omega_2$$ are the two zero points of $$f(\omega)$$. Thus $$f(\omega)$$ changes its plus-minus sign around five critical frequencies $$\omega_1, \omega_2, \omega_3,$$ and $$\omega_4$$.

Therefore, the pathway amplitudes can be coherently controlled by changing the six block phases. Our pathway manipulation strategy is tested for six cases with different objective functions with the results shown in Table I.

From the top panel of Fig.2, the conditions to maximize $$|U_1|, |U_2|, |U_3|, \text{ and } |\sum_{p} U_p|$$ can be easily extracted: $$\varphi_1 = \pi/2$$ and $$\varphi_2 = \varphi_3 = \varphi_4 = \varphi_5 = \varphi_6 = -\pi/2$$ for $$|U_1|$$ maximization; $$\varphi_1 = \varphi_3 = \varphi_6 = \varphi_4 = -\pi/2$$ for $$|U_2|$$ maximization; $$\varphi_1 = \varphi_2 = \varphi_3 = \varphi_4 = \varphi_5 = \pi/2$$ and $$\varphi_6 = -\pi/2$$ for $$|U_3|$$ maximization; $$\varphi_1 = \varphi_3 = \varphi_5 = \pi/2$$ and $$\varphi_2 = \varphi_4 = \varphi_6 = -\pi/2$$ for $$|\sum_{p} U_p|$$ maximization.

In consistent with the above analysis, Table I shows nearly the same simulation results for the first four cases, in which a finite difference-based gradient method is employed in the optimization. For the last three cases, the objective functions are chosen to be the pathway ratios to redirect the dynamics to desired pathways. The simulations turn out that we could keep the amplitude of the desired pathway the same order of magnitude as its maximal value in the first three cases, while suppressing the amplitudes of the other two pathways by several orders of magnitude.

For example, in last column, amplitude of pathway 3 is $$3.8636 \times 10^{-5}$$, which is just a little smaller than 5.1419 $$\times 10^{-5}$$, the best amplitude we could get, while the amplitude of pathways 1 and 2 are suppressed to less than 4 $$\times 10^{-11}$$. For TLPs, the pathway amplitudes are 5.4079 $$\times 10^{-7}$$ ($$|U_1|$$), 7.0474 $$\times 10^{-7}$$ ($$|U_2|$$), 5.4079 $$\times 10^{-7}$$ ($$|U_3|$$) and 1.9726 $$\times 10^{-6}$$ ($$|\sum_{p} U_p|$$).

Compared with TLPs, the objective functions can be improved by several orders of magnitude, which validates the success of this simple pathway manipulation strategy.

Above strategy can be extended to quantum systems with N intermediate states (|\psi_p\rangle, p=1, \ldots, N) connecting the initial (|\psi_0\rangle) and target (|\psi_{N+1}\rangle) states. The procedures can be summarized as the following three steps: (i) The phases at the resonant frequencies $$\omega_j$$ and $$\omega_{N+1} - \omega_p$$ are set to be zero. (ii) The whole spectrum is divided into 4N blocks, with the boundaries being $$\omega_p, \omega_{N+1} - \omega_p, \omega_{N/2}, \omega_c, \omega_{N+1} - \omega_c$$, where $$\omega_c$$ satisfies,

$$\sum_{p=1}^{N} \mu_p \mu_p^* \omega_p - \omega_c = 0$$ (20)

(iii) Only those of the first spectral 2N blocks are optimized, while the phases of the last 2N spectral blocks are fixed to zero. The strategy can effectively manipulate quantum control pathways via changing only 2N phase variables. It is simple and thus easy to implement in the experiments.

DOI:10.1063/1674-0068/28/cjcp1506124 ©2015 Chinese Physical Society
and only the phases of the first 2N blocks are optimized. An example with $N=3$ is given for demonstration. The strategy provides a practical choice for pathway manipulation in the optimal control experiments. It has to be noted that there are at most $N-1$ real roots, the number of spectral blocks could be less than $4N$, and further discussion is necessary.

IV. CONCLUSION

Coherent control of pathway is investigated in the perturbation regime for quantum systems with $N$ intermediate states connecting the initial and target states, and a simple but effective strategy is proposed. In the strategy, the overall spectrum is divided into $4N$ blocks, and only the phases of the first $2N$ blocks are optimized.
