Infrared photodissociation spectroscopy of mass-selected [MO(CO₂)ₙ]⁺ (M=Sc, Y, La) complexes indicates that the conversion from the solvated structure into carbonate one can be achieved by the ScO⁺ cation at n=5 and by the YO⁺ cation at n=4, while only the solvated structures are observed for the LaO⁺ cation. These findings suggest that both the ScO⁺ and YO⁺ cations are able to fix CO₂ into carbonate. Quantum chemical calculations are performed on [MO(CO₂)ₙ]⁺ to identify the structures of the low-lying isomers and to assign the observed spectral features. Theoretical analyses show that the [YO(CO₂)₄]⁺ complex has the smallest barrier for the conversion from the solvated structure into carbonate one, while [LaO(CO₂)₅]⁺ exhibits the largest conversion barrier among the three metal oxide cations. The present system affords a model in clarifying the effect of different metals in catalytic CO₂ transformation at the molecular level.

Key words: Infrared spectroscopy, CO₂ transformation, Metal monoxide cation

I. INTRODUCTION

The chemical conversion and fixation of carbon dioxide is one of the most extensively studied catalytic reactions because of their great environmental significance in global warming mitigation and various promising applications in synthetic and material chemistry [1–3]. Metal compounds play an important role in the catalytic transformation of CO₂ [4, 5]. Gas-phase optical spectroscopy of mass-selected clusters has provided great insights into the single-site catalysis processes at the molecular level [6–10].

The monodentate coordination M(η¹-CO₂), bidentate coordination M(η²-CO₂), or inserted OMCO structures have been observed in the neutral metal-CO₂ complexes [6, 11, 12]. In general, the weakly-bound M⁺-O-CO₂ structure is dominated in the interaction of CO₂ with a metal cation [7, 13–23]. Interestingly, the metal oxide-carbons [OMCO(CO₂)ₙ–1]⁺ (M=Ti, Ni, Si) present in the n≥5 clusters [16–18] and a bent CO₂⁻ fashion appears in [V(CO₂)₅]²⁻ (n≥7) [20, 24]. In the [M(CO₂)₄]⁻ cluster anions, the activation of CO₂ is very effectively achieved by the excess electron of the metal anion [8, 10, 25–35]. While the bidentate [M(η²-CO₂)]⁻ configuration is preferred for the first-row transition metal anions, the metalloformate [M(η¹-CO₂)]⁻ structure is favored for the Bi⁻, Cu⁻, Ag⁻, and Au⁻ anions [25, 26, 28, 30]. An oxalate motif has ever been captured in the [Bi(CO₂)₅]⁻ (n≥5) clusters [30]. Notable CO₂ activation is accessed in a Ni(II) compound [36] and a [ClMg(η²-O₂C)]⁻ complex [37].

Recent studies have shown that group III metal oxides are promising candidates for catalytic applications [2, 38, 39]. The reaction of YO⁺ with CO₂ was studied using ion beam mass spectrometry and its bond dissociation energy was measured to be (0.89±0.05) eV by collisional activation experiments with Xe [40]. Collision-induced dissociation experiments indicated that the [YO(CO₂)₄]⁺ complex consists of a weakly-bound structure [40]. Infrared photodissociation (IRPD) spectroscopic studies of [YO(CO₂)₄]⁺ reveal that the first three CO₂ molecules are weakly bound to YO⁺ and a carbonate motif is formed in the n≥4 clusters, which occurs via a solvation-induced electron transfer from the ligands to metal [41]. IRPD spectra of the [NbO₂(CO₂)₅]⁰⁺ and [TaO₂(CO₂)₅]⁰⁺ cluster cations show the dominant solvated structures, with some characteristic features of a possible carbonate moiety in the n≥4 clusters [42]. In the [TiO(CO₂)₅]⁻ cluster anions, the formation of carbonat, oxalato, oxo, n²-(O,O), and carbonyl ligands was identified [35]. Matrix-isolation IR spectroscopy of...
the neutral ScO with CO$_2$ has characterized a carbonate ScCO$_3$ complex [43]. Herein, we report an IR study on the interaction of CO$_2$ with the ScO$^+$ and LaO$^+$ cations using the IRPD spectroscopy and quantum chemical calculations. Combined with the preliminary study of the [YO(CO$_2$)$_n$]$^+$ system [41], the systematic experimental results show that CO$_2$ can be converted into carbonate by the ScO$^+$ and Yo$^+$ cations instead of LaO$^+$, which is supported by theoretical calculations.

II. EXPERIMENTS

IR spectra of the [MO(CO$_2$)$_n$]$^+$ (M=Sc and La) clusters are measured using an IRPD apparatus, which has been previously described in detail [41, 44]. The [MO(CO$_2$)$_n$]$^+$ complexes are prepared by a pulsed laser vaporization source with supersonic expansion of 2% O$_2$ seeded in CO$_2$. The cluster cations of interest are mass-selected and decelerated into the extraction region of a time-of-flight (TOF) mass spectrometer. Here, they interact with a single pass of the IR laser from a LaserVision OPO/OPA IR laser. The photodissociation fragments and parent cations are analyzed using the TOF mass spectrometer. Typical spectra are recorded by scanning the infrared laser in step of 2 cm$^{-1}$. The IRPD spectra are acquired by monitoring the fragment ions as a function of the wavelength of tunable infrared laser.

III. THEORETICAL METHOD

Electronic structure calculations are carried out using the Gaussian 09 program [45]. Recent study of the [YO(CO$_2$)$_n$]$^+$ complexes has shown that the B3LYP functional augmented with a dispersion correction (B3LYP-D) is able to reproduce the experimental IR spectroscopic observations [41]. Therefore, this functional is utilized for the present calculations as well. The DZP basis set is used for the carbon, oxygen, nitrogen, and hydrogen atoms, and the LanL2DZ ECP basis set for the scandium, yttrium, and lanthanum atoms. Tight convergence of the optimization and the self-consistent field procedures is imposed, and an ultrafine grid is used. To obtain relative energies and conversion barriers, the single point calculations are carried out at the B2PLYP(full)//def2-TZVP level based on the B3LYP-D/DZP-LanL2DZ optimized structures. The calculated IR spectra are derived from the B3LYP-D scaled harmonic frequencies (scaling factor: 0.964) [41] and are convoluted using a Gaussian line shape function with a 5 cm$^{-1}$ full width at half-maximum (FWHM).

FIG. 1 Experimental IRPD spectra of the [ScO(CO$_2$)$_n$]$^+$ ($n$=2–11) complexes.

FIG. 2 Experimental IRPD spectra of the [LaO(CO$_2$)$_n$]$^+$ ($n$=1–10) complexes.

IV. RESULTS AND DISCUSSION

The time-of-flight mass spectra of the products generated by a pulsed laser vaporization of scandium and lanthanum targets under the supersonic expansion are shown in FIG. S1 and FIG. S2 in supplementary materials, respectively. The metal monoxide-CO$_2$ cationic complexes in the form of [MO(CO$_2$)$_n$]$^+$ (M=Sc and La, $n$=1–15) are dominated in the mass spectral signals. Additional signals are assigned to the [M$_2$O$_2$(CO$_2$)$_n$]$^+$ species with relatively weak intensities as compared to [MO(CO$_2$)$_n$]$^+$.

Table a: antisymmetric stretch of \(\text{CO}_2\) in the first solvation shell, band b: antisymmetric stretch of \(\text{CO}_2\) in the second solvation shell, band c: \(\text{C}--\text{O}\) stretch of \(\text{CO}_2^{2-}\).

In the experimental IR spectra of \([\text{ScO(CO}_2\text{)}_n]^+\) \((n=2-11)\), \([\text{LaO(CO}_2\text{)}_n]^+\) \((n=1-10)\), respectively. The only fragmentation pathways observed involve loss of \(\text{CO}_2\). The nearly linear laser power dependence of the fragmentation signal is confirmed and the IR spectra are normalized according to the IR power. Band positions of \([\text{LaO(CO}_2\text{)}_n]^+\) \((n=1-4)\) are depicted in FIG. 4 and those of \([\text{LaO(CO}_2\text{)}_n]^+\) \((n=5-8)\) are shown in FIG. S3 (supplementary materials), respectively. The calculated band positions of \([\text{ScO(CO}_2\text{)}_n]^+\) and \([\text{LaO(CO}_2\text{)}_n]^+\) are given in Tables I and II, respectively.

Two binding motifs of solvated and carbonate structures are obtained, which are similar to those reported recently for the \([\text{YO(CO}_2\text{)}_n]^+\) system [41]. For \([\text{ScO(CO}_2\text{)}_n]^+\), the solvated structures, labeled nS in FIG. 3, are predicted to be the lowest in energy for the \(n=1-4\) clusters; the most stable isomer of the \(n=5\) cluster consists of a carbonate binding motif (labeled nC), which retains all of the lowest-energy isomers of the larger clusters. Similar features of minimum-energy structures are obtained for the \([\text{LaO(CO}_2\text{)}_n]^+\) clusters (FIG. 3). Slight structural difference is found in \([\text{ScO(CO}_2\text{)}_5]^+\) where one \(\text{CO}_2\) ligand is coordinated opposite to the carbonate or the oxygen on the axis. In contrast, all the four \(\text{CO}_2\) ligands are bound to the metal in the equatorial plane in \([\text{LaO(CO}_2\text{)}_5]^+\).

For the \([\text{ScO(CO}_2\text{)}_n]^+\) \((n=2-8)\) clusters, the agreement of the experimental IR spectra with the calculated ones (FIG. 1 and FIG. 4), in particular with the relative band positions and the size-dependent trends, is observed, supporting our initial assignments of these bands. The antisymmetric stretching vibrational frequencies of \(\text{CO}_2\) in the first solvation shell of the most stable isomers are predicted to be centered around 2360 cm\(^{-1}\) (Table I), which are consistent with the experimental values of band a. In the \([\text{ScO(CO}_2\text{)}_7]^+\) cluster, an antisymmetric stretch of \(\text{CO}_2\) in the second solv-
FIG. 3 Representatively optimized structures of the [ScO(CO\textsubscript{2})\textsubscript{n}]\textsuperscript{+} (\(n=2\text{–}8\)) and [LaO(CO\textsubscript{2})\textsubscript{n}]\textsuperscript{+} (\(n=1\text{–}8\)) complexes (Sc: white, La: cyan, C: gray, O: red). Relative energies are given in kJ/mol.
viation shell is calculated to be 2347 cm$^{-1}$, which also appears in the calculated IR spectra of the n=8 cluster, reproducing the experimental band b. In the calculated IR spectrum of the most stable structure for [ScO(CO$_2$)$_5$]$^+$ (5C), the band at 1833 cm$^{-1}$ is due to the C–O stretch of carbonate core, which is consistent with the experimental value of band c (1858 cm$^{-1}$) (Table I and FIGs. 1 and 4). The calculated frequency of band c red-shifts from 1833 cm$^{-1}$ to 1798 cm$^{-1}$ in-between the n=5 and n=8 clusters, which is in accord with the size-dependent trend observed in the experimental IR spectra.

For the [LaO(CO$_2$)$_n$]$^+$ (n=1–8) clusters, the calculated IR spectra of solvated structures (FIG. S3 in supplementary materials) are consistent with the experimental spectra (FIG. 2). In the calculated IR spectra of carbonate structures, the predicted C–O stretches of carbonate core are absent in the experimental spectra. It thus appears that the experimental spectra of [LaO(CO$_2$)$_n$]$^+$ (n=1–10) show the evidence of the formation of solvated structures, with the absence of carbonate structures.

The conversion barrier from the solvated structure into carbonate one of [MO(CO$_2$)$_5$]$^+$ calculated at the B2PLYP/def2-TZVP level for Sc, Y, and La is 28.9, 14.4, and 32.2 kJ/mol (FIG. 5), respectively. This indicates that the [YO(CO$_2$)$_5$]$^+$ complex has the smallest barrier for the conversion from the solvated structure into carbonate one, while [ScO(CO$_2$)$_5$]$^+$ exhibits a slightly larger conversion barrier, supporting the experimental observation of coordination-induced CO$_2$ fixation into carbonate by the ScO$^+$ and YO$^+$ cations. Note that the conversion barrier for the LaO$^+$+CO$_2$$_n$ system is not significantly larger than that for ScO$^+$ and YO$^+$, an alternative reason for the absence of carbonate formation in the LaO$^+$+CO$_2$$_n$ system could be that the conversion rate of solvated [LaO(CO$_2$)$_n$]$^+$ complex to carbonate [La(O)(CO$_2$)$_{n-1}$]$^+$ species is much slower than that of [ScO(CO$_2$)$_n$]$^+$ complex to carbonate [Sc(O)(CO$_2$)$_{n-1}$]$^+$ species. Recent gas-phase IRPD spectroscopy of the [Pt$_4$CO$_2$]$^-$ cluster identified a molecularly-adsorbed isomer instead of a fully-dissociated structure (the global minimum) [33]. Similarly, higher-energy isomers on the potential energy surface have also been observed in several cluster systems [46, 47].

As analyzed for the [YO(CO$_2$)$_n$]$^+$ system [41], the conversion of M=O and CO$_2$ undergoes a 2+2 cycloaddition transition state, and the negative charge on O is beneficial for its nucleophilic attacking to C center of CO$_2$ ligand. The CO$_2$ conversion from the solvated structure into carbonate one is assisted by donating electrons from the ligands to the metal. The conversion barrier decreases with the increase of cluster size. The Mulliken charges of metal and O atoms of the MO unit in the [MO(CO$_2$)$_n$]$^+$ solvated structures are given in Table S1 (supplementary materials). It can be seen from Table S1 that the difference in the Mulliken charge of metal atom is more prominent than that of O atom. The Sc and Y atoms are more electron rich than the La atom, suggesting a more favorable CO$_2$ carbonation, which is consistent with the present experimental observations.

Previous computational studies on the conversion of [YO(CO$_2$)$_8$]L$^+$ to [Y(CO$_2$)$_8$]L$^+$ (L=H$_2$O, NH$_3$, and N,N'-bis(methyl)imidazol-2-ylidine) indicated that the carbonation would become easier via the increase of the donating power of the ligand [41]. Further experimental investigation of CO$_2$ transformation in the ligand-doped [MO(CO$_2$)$_n$]L$^+$ systems is in progress. These studies would shed insights into molecular-level understanding of different degrees of activation of small molecules by tuning metals, ligands, cluster sizes, and supplementary materials.

V. CONCLUSION

Gas-phase vibrational spectroscopic and theoretical studies on the reaction of CO$_2$ with the ScO$^+$ and LaO$^+$ cations reveal that the CO$_2$ conversion from the solvated structure into carbonate one is observed for [ScO(CO$_2$)$_n$]$^+$ at n=5, while the CO$_2$ molecule is only weakly bound to the metal in [LaO(CO$_2$)$_n$]$^+$. Together with the recent study of the reaction of CO$_2$ with YO$^+$ [41], it can be found that the CO$_2$ fixation into carbonate is accessible by both ScO$^+$ and YO$^+$ rather than LaO$^+$. Theoretical analyses show that the [YO(CO$_2$)$_n$]$^+$ complex has the smallest barrier for the conversion from solvated structure into carbonate one, while [LaO(CO$_2$)$_n$]$^+$ exhibits the largest conversion barrier among the three metal oxide cations. The present system affords a model in clarifying how the coordination induces CO$_2$ fixation into carbonate by dif-
