(Dated: Received on May 26, 2011; Accepted on July 12, 2011)

Quasi-classical trajectory calculations have been employed to investigate the influence of collision energy on the stereodynamics of the title reaction C+CD→C₂+D on the potential energy surface of the 1^2A′ state developed by Boggio-Pasqua et al. [Mol. Phys. 98, 1925 (2000)]. The product angular distributions which reflect the vector correlation have been calculated. In addition, two polarization-dependent different cross-sections are also presented in the center-of-mass frame respectively. The results indicate that the product C₂ is sensitively affected by collision energy.

Key words: Quasi-classical trajectory, Stereodynamics calculation, Polarization dependent generalized differential cross-section, Stereodynamics

I. INTRODUCTION

Atom molecule reactions are important in a number of interesting situations including interstellar chemistry and upper atmosphere reactions [1, 2]. As a typical atom molecule reaction, the reaction C+CH→C₂H→C₂+H is selected mainly based on its importance in atmospheric chemistry and combustion [3–5]. Furthermore, the reaction can be considered as the prototype system to test the quality of new theories and experiments. Thus, the study of the reaction dynamics has received much attention recently, both experimentally [6–12] and theoretically [13–18].

Experimentally, in 1964, C₂H was first detected in argon matrixes [8]. Later, there have been extensive spectroscopic studies which mutually promoted the development of the understanding of the spectroscopy of C₂H [10, 11]. Using LIF method, Sorkhabi et al. studied the photodissociation of C₂H and estimated the branching ratios between the channels [12]. Theoretically, Boggio-Pasqua et al. presented the accurate adiabatic PESs by CASSCF calculations [13]. And the three lowest PESs are denoted 1^2A′, 2^2A′, and 1^2A″ [13, 14]. In order to understand the dynamics of the reaction C+CH fully, it is important to gain not only its scalar properties, but also its vector properties. In 2001, the time-dependent quantum wave packet method has been used to study the reaction C+CH on the 1A′ and 2A′ surface by Tang et al. [15, 16]. Recently, the stereodynamics of the C+CH, the vector correlations and polarization-dependent different cross-sections (PDD-CSSs) dependence on the collision energy and different PESs have been carried out by the quasi-classical trajectory (QCT) method [17, 18].

In order to obtain more information of this reaction, we investigated the C+CD→C₂+D system by the QCT method. We performed the theoretical dynamics calculations of the title reaction on the 1^2A′ PES, and analyzed the influence of the collision energies on the stereodynamics of this reaction.

II. THEORY

A. Quasi-classical trajectory calculations and potential energy surface

The calculated method in this work is the same as those described in the Refs. [19–22]. The QCT calculations code used in this work was provided by Professor Ke-li Han. The classical Hamilton’s equations were integrated numerically for motion in three dimensions. In our calculation, the collision energy ranging from 0.1 eV to 0.3 eV, with sixth order symplectic integration by running batches of 2×10⁴ trajectories. The trajectories were initialized at an C−CD internuclear separation of 10 Å. Vibrational and rotational levels of the reactants molecule are taken as v=0 and j=0, respectively. And the integration step size of 0.1 fs is used. In order to verify the accuracy of the numerical integration, the conservation of the total energy and total angular momentum for each trajectory have been checked.

In the present work, the product rotational polarization for the title reaction has been studied on the 1^2A′ PES constructed by Boggio-Pasqua et al. [14]. The
B. Product rotational polarization

The full angular distribution of the triple vector correlations \( k, k', j' \) of the product molecule are represented in the Fig.1 in the center-of-mass coordinate. In this coordinate, the reagent relative velocity \( k \) is parallel to the \( z \)-axis, and the \( y \)-axis is perpendicular to the \( x-z \) plane which contains the \( k \) and product relative velocity vector \( k' \). In order to fully describe the vector correlation of the reaction, the correlated center-of-mass function was written as [23–25].

\[
P(\cos \theta, \cos \theta_r, \phi_r) = \frac{1}{4\pi} \sum_{k=-\infty}^{\infty} \sum_{q=-k}^{k} (2k+1) \cdot \frac{2\pi}{\sigma} \frac{d\omega_k}{d\omega} C_{kq}(\theta_r, \phi_r)^* \tag{1}
\]

In Eq.(1), \( \omega_1=\theta_1, \phi_1 \) and \( \omega_r=\theta_r, \phi_r \) which are the polar coordinates of the unit vectors \( k' \) and \( j' \) in the CM frame. \( \sigma \) is the integral cross section and \( C_{kq}(\theta_r, \phi_r) \) represents the modified spherical harmonics. \( (1/\sigma)(d\sigma_{kq}/d\omega) \) is used to described the generalized PDDCSs. The detail functional form in this work can be referred to the literature [26–28]. In our investigation, we are only interested in the two PDDCSs \((2\pi/\sigma)(d\sigma_{00}/d\omega)\) and \((2\pi/\sigma)(d\sigma_{q0}/d\omega)\). The PDDCSs are expanded to \( k=7 \) for good convergence.

The usual two vector \( k-j' \) correlation distribution function \( P(\theta_r) \) which can be used to expand in a series of Legendre polynomials [29–31].

\[
P(\theta_r) = \frac{1}{2} \sum_{k} |k| a^k_0 P_k(\cos \theta_r) \tag{2}
\]

To understand the three vector correlation, the dihedral angle distributions of the \( k-k'-j' \), \( k-k'-1 \), and \( k-k'-1' \) are characterized by the angle \( \phi_1 \), \( 1 \) (the reagent orbital angular momentum), and \( 1' \) (the product orbital angular momentum), respectively. The distribution function

\[
P(\phi_r) \text{ can be expanded as a Fourier series [32–34].}
\]

\[
P(\phi_r) = \frac{1}{2\pi} \left( 1 + \sum_{n\text{even} \geq 2} a_n \cos n\phi_r + \sum_{n,\text{odd} \geq 1} b_n \sin n\phi_r \right) \tag{3}
\]

The joint probability density function \( P(\theta_r, \phi_r) \) reflecting the spatial distributions of product rotational angular momenta is given as follows:

\[
P(\theta_r, \phi_r) = \frac{1}{4\pi} \sum_{kq} |k| a^k_q C_{kq}(\theta_r, \phi_r)^* \cdot \sum_{q \geq 0} \left( a^k_{q\pm} \cos q\phi_r - a^k_{q\mp} i \sin q\phi_r \right) \cdot 
\]

\[
C_{kq}(\theta_r, 0) \quad a_n = 2 \langle \cos n\phi_r \rangle \tag{4}
\]

\[
b_n = 2 \langle \sin n\phi_r \rangle \tag{5}
\]

III. RESULTS AND DISCUSSION

The calculated results of distribution of \( P(\theta_r) \) dependence on collision energies of the title reaction are shown in Fig.2. The global reaction is barrierless relative to the reagent channel. We selected the collision energies at \( E_T=0.1, 0.2, \) and \( 0.3 \) eV. As we can see from Fig.2, the peak of \( P(\theta_r) \) is at \( \theta_r=90^\circ \) and symmetric about the right angle which can be attributed to the planar symmetry of the system. The observed results suggest that the product rotational angular momentum vector of the title reaction is strongly aligned along the direction perpendicular to the relative velocity direction. There is a contraction of the \( P(\theta_r) \) with the peak moving upwards, thus indicating the product rotational alignment effect becomes stronger with increasing of collision energies.
FIG. 3 The distribution of $P(\phi_r)$ describes the dihedral angle distribution of $j'$ with respect to the $k$-$k'$ plane at three collision energies.

The difference of $P(\theta_r)$ distributions dependence on the collision energies is in accordance with the results of the product rotational alignment parameter $\langle P_2(j', k) \rangle$. The calculated values of $\langle P_2(j', k) \rangle$ was $-0.473$, $-0.482$, and $-0.485$ with increasing collision energies ranging from 0.1 eV to 0.3 eV respectively, which leads to the stronger product rotational alignment.

In Fig.3, the dihedral angle distribution presenting the correlation of the $k$-$k'$-$j'$ has been calculated. There are two peaks at $90^\circ$ and $270^\circ$. The peak at $90^\circ$ becomes higher with increasing collision energies, while the opposite tendency occurs at $270^\circ$. At the 0.1 eV collision energy, the two peaks values almost the same. With the increasing of collision energies, considering the difference of the two peak at $90^\circ$ and $270^\circ$, we can deduce that the product rotational angular momentum vector $j'$ not only aligned, but also oriented along the $y$-axis. It is clear that the $P(\phi_r)$ distribution is asymmetric, which is probably attributed to the effect of the repulsive energy between C–D atoms. According to the previous theoretical “impulsive collision model” [35–37], the distribution of the product rotational angular momentum vector $j'$,

$$j' = L \sin^2 \beta + j \cos^2 \beta + J_1 m_A/m_B \quad (7)$$
$$J_1 = (\mu_{BC}R)^{1/2}r_{AB}r_{CB} \quad (8)$$

where $L$ is the reagent orbital angular momentum, $\mu_{BC}$ is the reduced mass of the BC molecular and $R$ is the repulsive energy. In the title reaction, the term of $L \sin^2 \beta + j \cos^2 \beta$ is symmetric while the $J_1 m_A/m_B$ term show a preferring direction for the effect of repulsive energy, which leads to the left handed product rotation in planes parallel to the scattering plane. The peak of $90^\circ$ increases with increasing of the collision energy, which can also be explained by the repulsive model. As described above, $J_1$ plays a crucial role in the product rotational orientation, large $J_1$ thus leads to stronger orientation along the $J_1$ direction. Because the repulsive energy $R$ increases with the collision energy, we can see that the modulus of $J_1$ becomes larger at high collision energy. Therefore, this influence plays a dominant part in product rotational orientation at high collision energy, thereby leading to the orientation along the positive direction of $y$-axis [38, 39].

The topographical features of the $P(\theta_r, \phi_r)$ distributions can be used to further support the above-mentioned vector correlations about the influence of collision energies differences on the stereodynamics of the products.

FIG. 4 Polar plots of $P(\theta_r, \phi_r)$ distribution averaged over all scattering angles for three collision energies. (a) $E_T=0.1$ eV, (b) $E_T=0.2$ eV, (c) $E_T=0.3$ eV.
title reaction. As can be seen from Fig.4, the distributions of $P(\theta_r, \phi_r)$ with a peak at $90^\circ$ and $270^\circ$ are in good accordance with the distributions of $P(\theta_r)$ and $P(\phi_r)$ of the $C_2$ products for three collision energies.

Figure 5 plots the generalized PDDCSs which are used to depict the $\mathbf{k'}$-$\mathbf{j'}$ correlation and the scattering direction of the products as a function of scattering angle $\theta_t$. The PDDCSs of product $(2\pi/\sigma)(d\sigma_{00}/d\sigma_{20})$ and $(2\pi/\sigma)(d\sigma_{20}/d\sigma_{00})$ are drawn in Fig.5(a). Further, PDDCSs are not completely symmetric with a forward scattering bias. The backward-forward asymmetry may be attributed to the exothermic feature of the reactions. As simple the differential cross-section, the PDDCSs are not completely symmetric with a forward scattering bias. The backward-forward asymmetry may be attributed to the exothermic feature of the reactions. 

IV. CONCLUSION

In this work, the stereodynamics of the reaction $\text{C}_2+\text{CD} \rightarrow \text{C}_2+\text{D}$ has been investigated by the QCT method. We present the vector correlation of $P(\theta_r)$, $P(\phi_r)$, and $P(\theta_r, \phi_r)$. There is a contraction of the $P(\theta_r)$ with the peak moving upwards, thus indicating the product rotational alignment effect becomes stronger with increasing of collision energies. With the increasing of collision energies, considering the difference of the two peak of $P(\phi_r)$ at $90^\circ$ and $270^\circ$, we can deduce that the product rotational angular momentum vector $\mathbf{j'}$ not only aligned, but also oriented along the $y$-axis. In addition, with the increasing of collision energies, degree of PDDCSs forward scattering whereas that of backward scattering is also strongly affected by collision energies.
